GR 99 P 4784

Abstract

Method for conversion of a voice appliance output of
statuses

For a voice output of appliance statuses, three spoken
phrases are stored for each appliance to be controlled,
with the first spoken phrase being allocated to a first
appliance status, the second spoken phrase being
allocated to a second appliance status, and the third
spoken phrase being allocated for at least one third
status. When an appliance status is checked, the
relevant appliance sends a data word. If the value
(which identifies the current appliance status) of the
data word corresponds to a first value, the first
spoken phrase is output, if it corresponds to a second,
the second spoken phrase is output, and the third
spoken phrase and the third value are output for at
least one third value.
